**“IT’S TOUGH TO MAKE  
PREDICTIONS, ESPECIALLY  
ABOUT THE FUTURE.”**

*–Yogi Berra*

(A similar phrase is attributed to Niels Bohr, Danish physicist and winner of the Nobel Prize in 1922)

# Forecasting

*(AR, MA, ARMA, ARIMA, ...)*

# Stationary vs Non-Stationary processes

- **Stationary process**
  - Parameters do not change over time
  - E.g., *White noise* has zero mean, fixed variance, and zero covariance between  $y_t$  and  $y_{t+L}$  for any lag  $L$
- **Non-stationary process**
  - Parameters change over time
  - E.g., price of oil, height of a child, glucose level of a patient, ...

# Stationary process

# Non-stationary process

# Strictly stationary time series

A **strictly stationary time series** is one in which the distribution of values in any time interval  $[a, b]$  is identical to that in  $[a+L, b+L]$  for any value of time shift (lag)  $L$

- In this case, current parameters (e.g., mean) are good predictors of future parameters

# Differencing

First order differencing

$$y'_i = y_i - y_{i-1}$$

In this first example, if the original series is superlinear, the differenced series is stationary or non-stationary?

# Differencing (cont.)

First order differencing

$$y'_i = y_i - y_{i-1}$$

In this second example, where the series is linear, the differenced series is stationary or non-stationary?

# Other differencing operations

- Second-order differencing

$$\begin{aligned}y_i'' &= y_i' - y_{i-1}' \\ &= y_i - 2 \cdot y_{i-1} + y_{i-2}\end{aligned}$$

- $y_i' = y_i - y_{i-m}$  **encing** ( $m = 24 \text{ hours, } 7 \text{ days, } \dots$ )

If you find a differencing that yields a stationary series, the forecasting problem is basically solved.

# Autoregressive model AR(p)

$$\text{Autocorrelation}(L) = \frac{\text{Covariance}_t(y_t, y_{t+L})}{\text{Variance}_t(y_t)}$$

- Autocorrelation lines in  $[-1,1]$
- High absolute values  $\Rightarrow$  predictability
- Autoregressive model of order  $p$ , AR(p):

$$y_t^{\text{AR}} = \sum_{i=1}^p a_i \cdot y_{t-i} + c + \epsilon_t$$

# How to decide $p$ ? Autocorrelation plots

(a) IBM stock

(b) Sine wave

What is a reasonable range for  $p$  in these cases?

# Finding coefficients and evaluating

- Each data point is a  $y_t^{\text{AR}} = \sum_{i=1}^p a_i \cdot y_{t-i} + c + \epsilon_t$   
training element

- Coefficients found by least-squares regression

- Best models have  $R^2 = 1 - \frac{\text{Mean}_t(\epsilon_t^2)}{\text{Variance}_t(y_t)}$

# Exercise

- Create a simple auto-regressive model
- Use two lags:
  - 1 hour
  - 24 hours
- Compute the predicted series  
(optionally: include it in the plot)
- Compute the maximum error

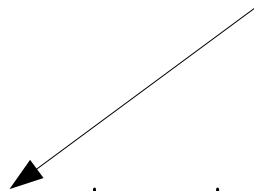

Answer in  
Google Spreadsheet

# Moving average model MA(q)

- Focus on the variations (shocks) of the model, i.e., places where **change was unexpected**

- AR(p) model: 
$$y_t^{\text{AR}} = \sum_{i=1}^p a_i \cdot y_{t-i} + c + \epsilon_t$$

- MA(q) model: 
$$y_t^{\text{MA}} = \sum_{i=1}^q b_i \cdot \epsilon_{t-i} + c + \epsilon_t$$

# Autoregressive moving average model

## ARMA(p,q)

- Combines both the autoregressive and the moving average model

$$y_t^{\text{ARMA}} = \sum_{i=1}^p a_i \cdot y_{t-i} + \sum_{i=1}^q b_i \cdot \epsilon_{t-i} + c + \epsilon_t$$

- Select small p, q, to avoid overfitting

# Autoregressive integrated moving average model ARIMA(p,q)

- Combines both the autoregressive and the moving average model on differenced series

$$y_t^{\text{ARIMA}} = \sum_{i=1}^p a_i \cdot (y_{t-i} - y_{t-i-1}) + \sum_{i=1}^q b_i \cdot \epsilon_{t-i} + c + \epsilon_t$$

Note: this is an ARIMA(p,1,q) model as we're using first order differencing

# Event detection

## (a simple framework)

# Event: an important occurrence

Earthquake or  
aftershock

Droplet  
release

Sudden  
price change

# Example: pipe rupture

(a) Temperature (pipe rupture scenario)

(b) Pressure (pipe rupture scenario)

# (... but what if sensors fail? ...

- “Systems in general work poorly or not at all”
- “In complex systems, malfunction and even total non-function may not be detectable for long periods, if ever”

Gall, John. Systemantics: the underground text of systems lore: how systems really work and especially how they fail. Ann Arbor, MI, 1975.

# ... can we detect failure? ...)

(c) Temperature (sensor failure scenario)

(d) Pressure (sensor failure scenario)

# A general scheme for event detection in multivariate time series

- Let  $T_1, T_2, \dots, T_r$  be times at which an event has been observed in the past
- (Offline) Learn coefficients  $\alpha_1, \alpha_2, \dots, \alpha_d$  to distinguish between event times and non-event times
- (Online) Observe series and determine deviation of every stream  $i$  at timestamp  $t$  as  $z_t^i$
- (Online) Compute composite alarm level

$$Z_t = \sum_{i=1}^d \alpha_i \cdot z_t^i$$

# Learning discrimination coefficients $\alpha_1$ ,

$$\alpha_2, \dots, \alpha_d$$

- Average alarm level for events

$$Q^{\text{event}}(\alpha_1, \dots, \alpha_d) = \frac{1}{r} \sum_{i=1}^r Z_{T^i}$$

$$Z_t = \sum_{i=1}^d \alpha_i \cdot z_t^i$$

- Average alarm level for non-events

(we as

$$Q^{\text{normal}}(\alpha_1, \dots, \alpha_d) = \frac{1}{N} \sum_{t=1}^N Z_t)$$

# Learning discrimination coefficients $\alpha_1$ ,

$\alpha_2, \dots, \alpha_d$  (cont.)

- For events

$$Q^{\text{event}}(\alpha_1, \dots, \alpha_d) = \frac{1}{r} \sum_{i=1}^r Z_{T^i}$$

- For non-events

$$Q^{\text{normal}}(\alpha_1, \dots, \alpha_d) = \frac{1}{N} \sum_{i=1}^N Z_t$$

Maximize

$$Q^{\text{event}}(\alpha_1, \dots, \alpha_d) - Q^{\text{normal}}(\alpha_1, \dots, \alpha_d)$$

subject to

$$\sum_{i=1}^d \alpha_i^2 = 1$$

Use any off-the-shelf iterative  
optimization solver

# Summary

# Things to remember
